# FARM MANAGEMENT SYSTEM

Salesforce-Based Agricultural Data Management Project

## REWRITTEN ALTERNATIVE VERSION

*Project overview / architecture reference*

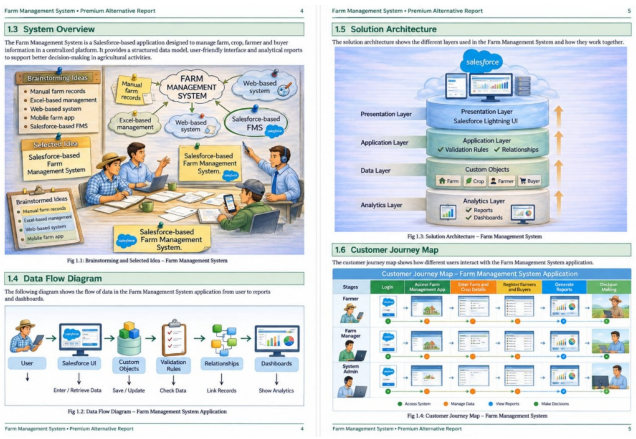

45-page version with alternative wording, the same project scope, and the supplied Salesforce implementation screenshots.

# 1. PROJECT OVERVIEW

The Farm Management System is a Salesforce-based solution created to organize agricultural information in a centralized digital environment. The project brings together farm, crop, farmer and buyer records so that important information can be entered, updated and reviewed systematically. Instead of depending on separate registers, users can work with connected Salesforce records.

The application focuses on structured data management, validation, relationships, access control, reports and dashboards. These components work together to support day-to-day farm information handling and provide a foundation for better monitoring of agricultural activities.

The system is designed around the needs of farmers, farm managers, buyers and system administrators. Each user group interacts with information according to its operational requirement and access level.

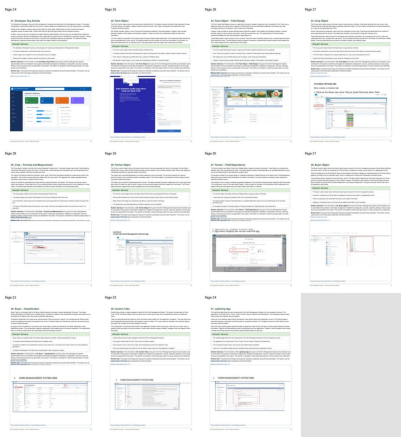

*Salesforce project screenshot / implementation reference*

# 2. INTRODUCTION

Agricultural activities generate different types of information, including farm details, crop production information, farmer contact details and buyer information. When such information is maintained manually, searching, updating and comparing records can become difficult. A centralized digital platform provides a more organized method of maintaining these records.

The Farm Management System uses Salesforce to create this centralized environment. Custom objects are used for Farm, Crop, Farmer and Buyer information. Relationships connect these records so that related information can be viewed and reported together.

The project also includes validation, profiles, roles, users, sharing rules, reports and dashboards. These features make the system more structured and support controlled access to agricultural data.

*Salesforce project screenshot / implementation reference*

# 3. PROJECT PURPOSE

The primary purpose of the project is to digitize agricultural record management through Salesforce. The system aims to reduce dependence on paper-based records and provide a consistent structure for storing information.

Another purpose is to make information easier to retrieve. When records are stored in related Salesforce objects, users can review information according to the farm, crop, farmer or buyer involved. This organization can reduce repeated manual searching.

The project also aims to support analysis. Reports and dashboards transform stored records into summarized information that can be reviewed by authorized users. This creates a connection between data entry and decision support.

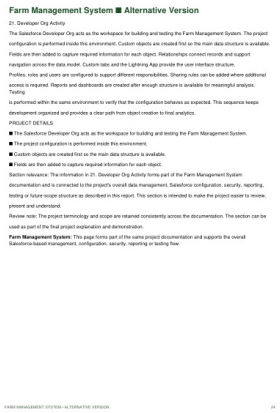

*Salesforce project screenshot / implementation reference*

# 4. USER STORY

The project user story describes the requirement from the perspective of the people using the system. A farmer, farm manager or system administrator needs a centralized Salesforce platform for recording and managing farm, crop, farmer and buyer information.

Users need to enter and update information through a user-friendly interface with suitable validation. They also need reports and interactive dashboards for reviewing farm productivity and sales-related information.

The story additionally emphasizes role-based access and secure storage. The intended outcome is a reduction in manual paperwork, fewer data-entry errors, improved efficiency and more systematic agricultural information management.

Farm Management System ■ Alternative Version

21. Developer Org Activity

The Salesforce Developer Org acts as the workspace for building and testing the Farm Management System. The project configuration is performed inside this environment. Custom objects are created first so the main data structure is available. Fields are then added to capture required information for each object. Relationships connect records and support navigation across the data model. Custom tabs and the Lightning App provide the user interface structure. Profiles, roles and users are configured to support different responsibilities. Sharing rules can be added where additional access is required. Reports and dashboards are created after enough structure is available for meaningful analysis. Testing is performed within the same environment to verify that the configuration behaves as expected. This sequence keeps development organized and provides a clear path from object creation to final analytics.

PROJECT DETAILS

■ The Salesforce Developer Org acts as the workspace for building and testing the Farm Management System.
■ The project configuration is performed inside this environment.
■ Custom objects are created first so the main data structure is available.
■ Fields are then added to capture required information for each object.

Section relevance: The information in 21. Developer Org Activity forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration , security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM • ALTERNATIVE VERSION 24

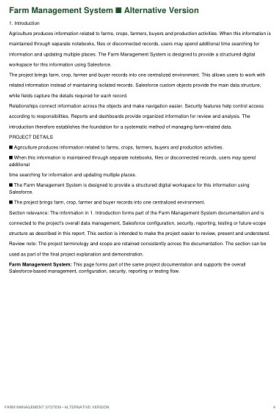

*Salesforce project screenshot / implementation reference*

# 5. PROBLEM STATEMENT

The first problem area concerns maintaining farm and crop records. Manual records may be incomplete, difficult to update or difficult to retrieve. A farmer needs a structured method to maintain important information without repeatedly depending on paper registers.

The second problem concerns farm managers who need to review information across different farms and crops. Without connected records, preparing a consolidated view can require additional manual effort.

The buyer and administrator requirements create additional needs. Buyer details must be maintained accurately, while administrators need to control user access and system configuration. These combined requirements lead to the need for a centralized Salesforce application.

**Farm Management System ■ Alternative Version**

1. Introduction

Agriculture produces information related to farms, crops, farmers, buyers and production activities. When this information is maintained through separate notebooks, files or disconnected records, users may spend additional time searching for information and updating multiple places. The Farm Management System is designed to provide a structured digital workspace for this information using Salesforce.

The project brings farm, crop, farmer and buyer records into one centralized environment. This allows users to work with related information instead of maintaining isolated records. Salesforce custom objects provide the main data structure, while fields capture the details required for each record.

Relationships connect information across the objects and make navigation easier. Security features help control access according to responsibilities. Reports and dashboards provide organized information for review and analysis. The introduction therefore establishes the foundation for a systematic method of managing farm-related data.

PROJECT DETAILS

■ Agriculture produces information related to farms, crops, farmers, buyers and production activities.

■ When this information is maintained through separate notebooks, files or disconnected records, users may spend additional

time searching for information and updating multiple places.

■ The Farm Management System is designed to provide a structured digital workspace for this information using Salesforce.

■ The project brings farm, crop, farmer and buyer records into one centralized environment.

Section relevance: The information in 1. Introduction forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration, security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM • ALTERNATIVE VERSION 4

*Salesforce project screenshot / implementation reference*

# 6. BRAINSTORMING

The project considered multiple approaches before selecting the proposed solution. Ideas included manual farm records, Excel-based management, a web-based system, a mobile farm application and a Salesforce-based Farm Management System.

Manual records can be familiar but make centralized access and reporting difficult. Spreadsheet-based management can organize information but may become difficult to maintain as the number of records grows.

The selected idea is a Salesforce-based Farm Management System. The selection aligns with the project requirement for custom objects, relationships, validation, access control, reports and dashboards within one platform.

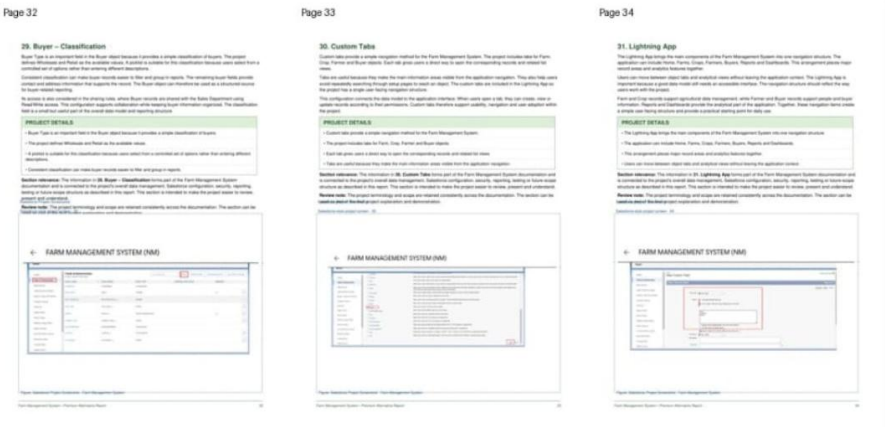

*Salesforce project screenshot / implementation reference*

# 7. CUSTOMER JOURNEY

The customer journey begins with Login. Authentication provides the starting point for controlled access to the Salesforce environment. After login, the user accesses the Farm Management application through the available navigation.

The next activities are entering farm and crop information and registering farmers and buyers. These activities create the main records used by the application.

The final stages are generating reports and analyzing results. This shows how the system moves from data entry to organized information and then to review through analytics.

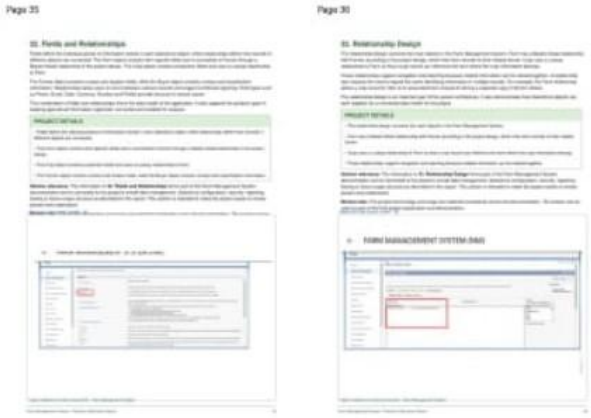

*Salesforce project screenshot / implementation reference*

# 8. FUNCTIONAL REQUIREMENTS

The project identifies seven functional requirements. FR-1 covers User Authentication. FR-2 covers Farm, Crop, Farmer and Buyer Management. FR-3 covers Data Entry and Validation.

FR-4 covers Relationship Mapping. FR-5 covers Report Generation. FR-6 covers Dashboard Visualization. FR-7 covers User Role Management.

Together these requirements describe the major capabilities of the system. They provide a clear connection between the identified user needs and the Salesforce configuration activities.

*Salesforce project screenshot / implementation reference*

# 9. NON-FUNCTIONAL REQUIREMENTS

The system also requires qualities that support reliable use. Information should be organized and protected through suitable Salesforce access mechanisms. The interface should allow users to work with records in a consistent manner.

Data quality is supported through appropriate field types, required information, validation and relationships. The application should also provide reports and dashboards that can be accessed by authorized users.

These requirements complement the functional features and help establish a practical structure for the Farm Management System.

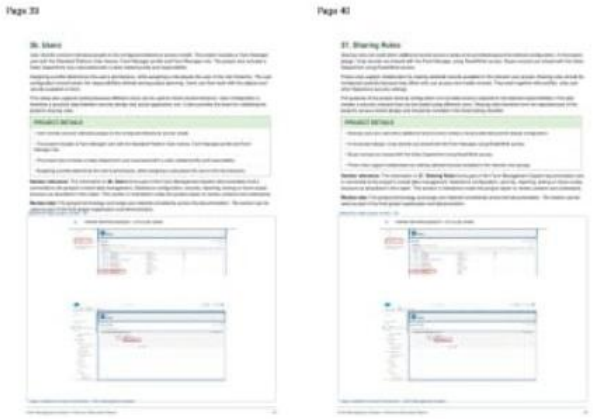

*Salesforce project screenshot / implementation reference*

# 10. FARM OBJECT

The Farm object represents individual farms within the Salesforce application. Farm Type is configured as a picklist containing Crop, Livestock and Mixed. This allows the type of farm to be selected from predefined values.

Soil Quality is maintained with values such as Organic, Cover Crops and Composting. Irrigation Type includes Sprinkler irrigation, Drip irrigation and localized irrigation. Location and Size are also maintained as farm information.

The Farm object has a Master-Detail relationship with Farmer. This relationship connects a farm record with the farmer information maintained in the system.

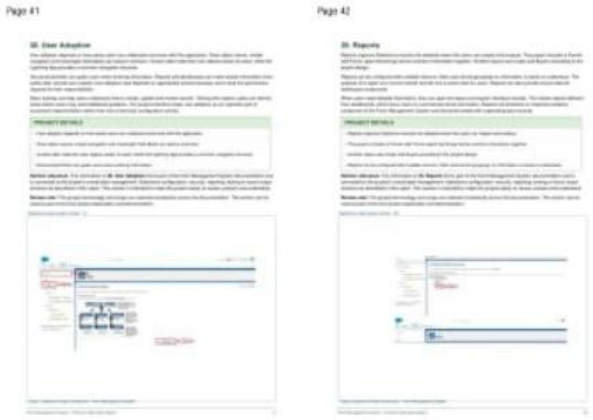

*Salesforce project screenshot / implementation reference*

# 11. CROP OBJECT

The Crop object is used to maintain production-related information. Crop Name identifies the crop, while Planting Date and Harvest Date record important dates in the crop cycle.

Actual Yield records the yield value and Total Acres Harvested records the harvested area. A Lookup relationship connects the Crop object with Farm so that crop information can be associated with a particular farm.

The project also uses a formula field for Expected Yield per Acre. The calculation is based on Actual Yield divided by Total Acres Harvested, providing a derived value from the stored records.

*Salesforce project screenshot / implementation reference*

# 12. FARMER OBJECT

The Farmer object stores information about farmers who are associated with farms. Contact Number is maintained as a phone field so that contact information follows a suitable Salesforce data type.

State is configured as a picklist containing Telangana, Andhra Pradesh and Tamilnadu. District and Village information are maintained as location-related fields.

The object demonstrates how structured fields can reduce inconsistent data entry. Location information can be selected through configured values rather than being entered in completely different formats each time.

*Salesforce project screenshot / implementation reference*

# 13. FIELD DEPENDENCY

Field dependency is used in the Farmer object to control related location selections. State acts as the controlling field while District acts as a dependent field. This arrangement helps present relevant district choices based on the selected state.

The project includes an example configuration in which Telangana is associated with Yadadri Bhongir. The dependency demonstrates how Salesforce can guide users during data entry.

Using dependent selections can reduce unsuitable combinations and improve consistency in location information. It also makes the form more structured for users.

Farm Management System ■ Alternative Version

31. Lightning App

The Lightning App brings the main components of the Farm Management System into one navigation structure. The application can include Home, Farms, Crops, Farmers, Buyers, Reports and Dashboards. This arrangement places major record areas and analytics features together.

Users can move between object tabs and analytical views without leaving the application context. The Lightning App is important because a good data model still needs an accessible interface. The navigation structure should reflect the way users work with the project.

Farm and Crop records support agricultural data management, while Farmer and Buyer records support people and buyer information. Reports and Dashboards provide the analytical part of the application. Together, these navigation items create a simple user-facing structure and provide a practical starting point for daily use.

PROJECT DETAILS

■ The Lightning App brings the main components of the Farm Management System into one navigation structure.

■ The application can include Home, Farms, Crops, Farmers, Buyers, Reports and Dashboards.

■ This arrangement places major record areas and analytics features together.

■ Users can move between object tabs and analytical views without leaving the application context.

Section relevance: The information in 31. Lightning App forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration, security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 34

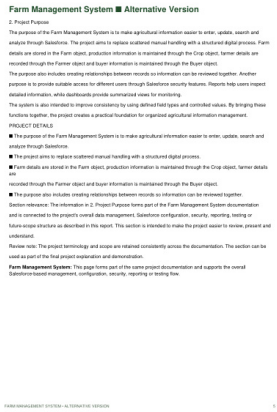

*Salesforce project screenshot / implementation reference*

# 14. BUYER OBJECT

The Buyer object is designed to maintain buyer information. It includes Contact, Email and Address fields for communication and identification purposes.

Buyer Type is a picklist with Wholesale and Retail values. Using predefined categories helps standardize buyer classification and makes the information easier to use in reports.

Buyer records can also participate in controlled access through sharing rules. In the project, Buyer information is shared with the Sales Department using Read/Write access, supporting authorized collaboration.

Farm Management System ■ Alternative Version

2. Project Purpose

The purpose of the Farm Management System is to make agricultural information easier to enter, update, search and analyze through Salesforce. The project aims to replace scattered manual handling with a structured digital process. Farm details are stored in the Farm object, production information is maintained through the Crop object, farmer details are recorded through the Farmer object and buyer information is maintained through the Buyer object.

The purpose also includes creating relationships between records so information can be reviewed together. Another purpose is to provide suitable access for different users through Salesforce security features. Reports help users inspect detailed information, while dashboards provide summarized views for monitoring.

The system is also intended to improve consistency by using defined field types and controlled values. By bringing these functions together, this project creates a practical foundation for organized agricultural information management.

PROJECT DETAILS

■ The purpose of the Farm Management System is to make agricultural information easier to enter, update, search and analyze through Salesforce.

■ The project aims to replace scattered manual handling with a structured digital process.

■ Farm details are stored in the Farm object, production information is maintained through the Crop object, farmer details are

recorded through the Farmer object and buyer information is maintained through the Buyer object.

■ The purpose also includes creating relationships between records so information can be reviewed together.

Section relevance: The information in 2. Project Purpose forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration, security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 5

*Salesforce project screenshot / implementation reference*

# 15. OBJECT RELATIONSHIPS

Relationships connect the main objects and allow the application to represent how agricultural information is associated. Farm is connected to Farmer using a Master-Detail relationship.

Crop is connected to Farm using a Lookup relationship. This allows crop information to reference the farm where the crop is maintained or produced.

Relationships are important for reporting as well. A report can combine information from related objects, such as farmers and their farms. This creates a more useful view than isolated records.

*Salesforce project screenshot / implementation reference*

# 16. DATA VALIDATION

Data validation is used to prevent unsuitable information from being stored. Salesforce field types, picklists, dependencies and required fields provide basic controls at the point of entry.

The project also uses formula logic for calculated information. For example, Expected Yield per Acre is derived from Actual Yield and Total Acres Harvested instead of requiring a separate manual calculation.

Validation supports data quality by reducing inconsistent entries. Testing should include both valid and invalid values so that configured controls can be confirmed.

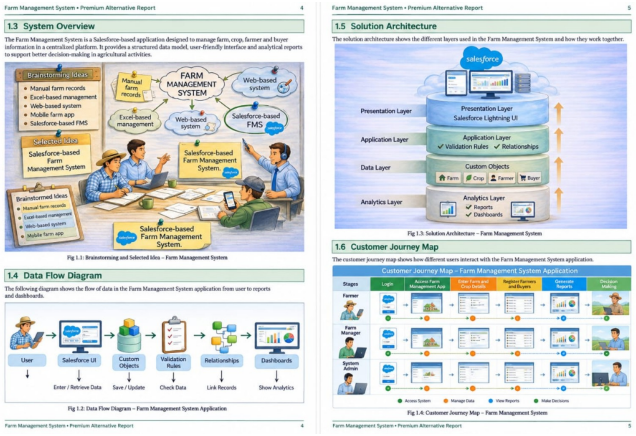

*Salesforce project screenshot / implementation reference*

# 17. SALESFORCE DEVELOPER ORG

The project is implemented inside a Salesforce Developer Org. The development environment provides the platform required for creating custom objects, fields, relationships and application configuration.

The implementation begins by accessing Salesforce using the configured account. The Salesforce interface provides Setup and Object Manager features for creating and managing project components.

Using a Developer Org allows the project configuration to be developed and tested before it is considered as a complete application environment.

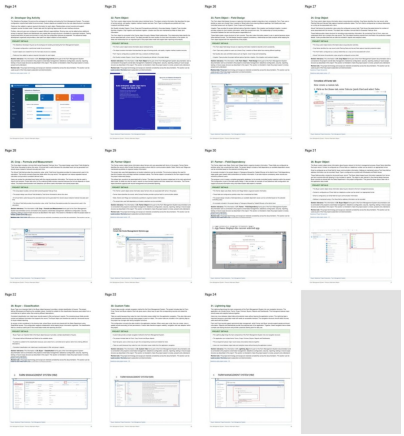

*Salesforce project screenshot / implementation reference*

# 18. CUSTOM OBJECT CREATION

Custom objects are created to represent the main business areas of the Farm Management System. Farm, Crop, Farmer and Buyer are the central objects used by the project.

Each object is designed with its own fields and data types so that the required information can be stored consistently. After object creation, relationships and other configuration elements can be added.

This object-based structure forms the foundation of the Salesforce data model and supports later navigation, reporting, validation and access-control activities.

*Salesforce project screenshot / implementation reference*

# 19. FIELD DESIGN

Field design defines the information stored in each custom object. Suitable field types, picklists, date fields, phone fields, email fields, text areas and calculated fields are used according to the project's data requirements.

The field configuration provides a consistent structure for records and makes the information easier to search, filter and report. Controlled values also reduce variations in data entry.

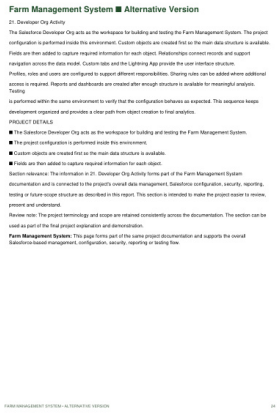

*Salesforce project screenshot / implementation reference*

# 20. FARM OBJECT FIELD DESIGN

The Farm object uses fields for Farm Type, Soil Quality, Irrigation Type, Location and Size. Picklists provide controlled choices for the categorical fields.

The Farmer relationship connects the farm to its responsible farmer. Together, these fields provide the basic information required to describe a farm within the application.

**Farm Management System ■ Alternative Version**

21. Developer Org Activity

The Salesforce Developer Org acts as the workspace for building and testing the Farm Management System. The project configuration is performed inside this environment. Custom objects are created first so the main data structure is available. Fields are then added to capture required information for each object. Relationships connect records and support navigation across the data model. Custom tabs and the Lightning App provide the user interface structure. Profiles, roles and users are configured to support different responsibilities. Sharing rules can be added where additional access is required. Reports and dashboards are created after enough structure is available for meaningful analysis. Testing

is performed within the same environment to verify that the configuration behaves as expected. This sequence keeps development organized and provides a clear path from object creation to final analytics.

PROJECT DETAILS

■ The Salesforce Developer Org acts as the workspace for building and testing the Farm Management System.

■ The project configuration is performed inside this environment.

■ Custom objects are created first so the main data structure is available.

■ Fields are then added to capture required information for each object.

Section relevance: The information in 21. Developer Org Activity forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration , security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

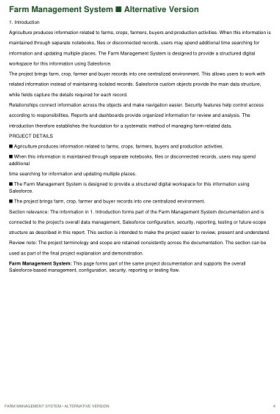

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 24

*Salesforce project screenshot / implementation reference*

# 21. CROP FORMULA AND MEASUREMENT

The Crop object includes Actual Yield and Total Acres Harvested as stored measurements. Expected Yield per Acre is derived using the project formula based on these values.

A formula field avoids repeated manual calculation and keeps the derived value connected to the underlying record. The result can also be used in reporting and analysis.

Farm Management System ■ Alternative Version

1. Introduction

Agriculture produces information related to farms, crops, farmers, buyers and production activities. When this information is maintained through separate notebooks, files or disconnected records, users may spend additional time searching for information and updating multiple places. The Farm Management System is designed to provide a structured digital workspace for this information using Salesforce.

The project brings farm, crop, farmer and buyer records into one centralized environment. This allows users to work with related information instead of maintaining isolated records. Salesforce custom objects provide the main data structure, while fields capture the details required for each record.

Relationships connect information across the objects and make navigation easier. Security features help control access according to responsibilities. Reports and dashboards provide organized information for review and analysis. The introduction therefore establishes the foundation for a systematic method of managing farm-related data.

PROJECT DETAILS

■ Agriculture produces information related to farms, crops, farmers, buyers and production activities.

■ When this information is maintained through separate notebooks, files or disconnected records, users may spend additional

time searching for information and updating multiple places.

■ The Farm Management System is designed to provide a structured digital workspace for this information using Salesforce.

■ The project brings farm, crop, farmer and buyer records into one centralized environment.

Section relevance: The information in 1. Introduction forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration, security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 4

*Salesforce project screenshot / implementation reference*

# 22. BUYER CLASSIFICATION

Buyer Type provides a controlled classification for buyer records. The project uses Wholesale and Retail as the available choices.

A picklist keeps classification consistent and makes filtering or grouping buyer information easier when reports are prepared. The field therefore supports both data quality and reporting.

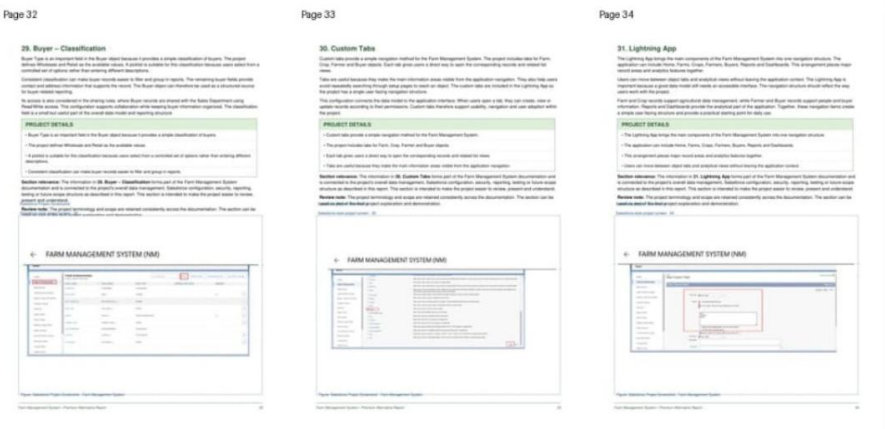

*Salesforce project screenshot / implementation reference*

# 23. CUSTOM TABS

Custom tabs provide direct navigation to the Farm, Crop, Farmer and Buyer objects. Users can open the required record area without repeatedly moving through setup pages.

The tabs connect the Salesforce data model to the user-facing application and support easier record creation, viewing and updating.

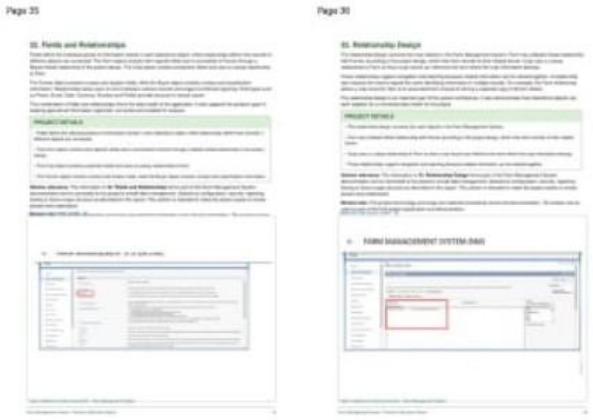

*Salesforce project screenshot / implementation reference*

# 24. LIGHTNING APP

The Lightning App brings the major project components into one navigation structure. The application can include Home, Farms, Crops, Farmers, Buyers, Reports and Dashboards.

This arrangement gives users a common place to work with records and analytics. It connects the project's data model with an accessible interface.

*Salesforce project screenshot / implementation reference*

# 25. SOLUTION ARCHITECTURE

The solution can be understood as connected layers. Users interact with the Salesforce Lightning interface, which provides access to the custom objects and their fields.

Relationships and security settings control how information is connected and accessed. Reports and dashboards form the analytics layer and use stored project records for review.

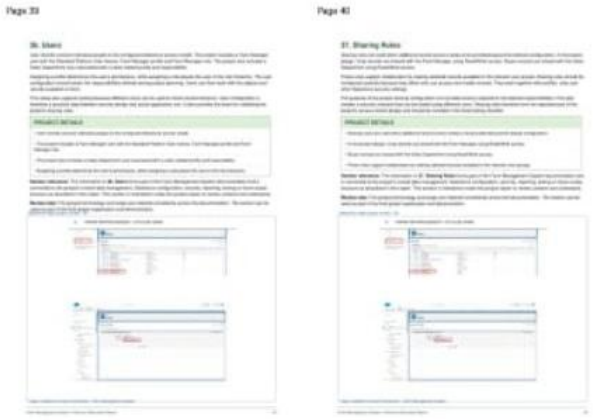

*Salesforce project screenshot / implementation reference*

# 26. PROJECT PLANNING

Implementation is organized into stages. Requirement analysis establishes the project scope, followed by creation of the four main custom objects.

Interface configuration, field and relationship setup, security configuration, analytics and testing follow as later stages. This sequence gives the project a clear implementation path.

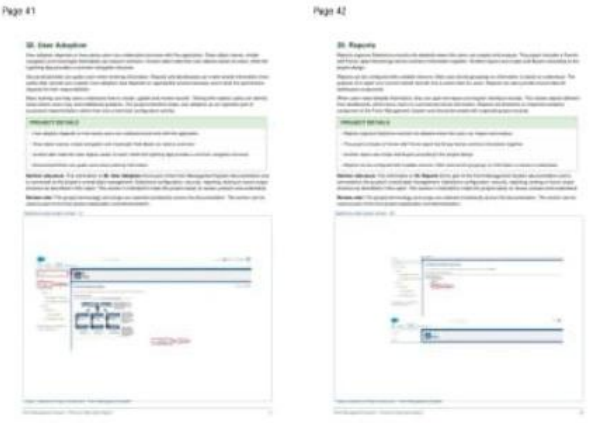

*Salesforce project screenshot / implementation reference*

# 27. PRODUCT BACKLOG

The product backlog lists the main configuration activities required for completion. Object creation is followed by tabs, Lightning App navigation, fields and relationships.

Security activities include profiles, role hierarchy, users and sharing rules. Reports, dashboards and testing complete the main implementation checklist.

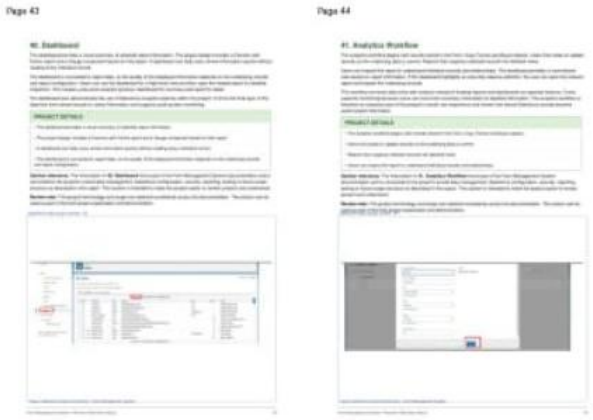

*Salesforce project screenshot / implementation reference*

# 28. SPRINT PLAN

The project can be organized into practical sprints. Early work covers requirements and object creation, followed by interface and data-model configuration.

Later sprints focus on security, analytics and testing. Dividing the work into stages makes progress easier to track and review.

*Salesforce project screenshot / implementation reference*

# 29. SALESFORCE PLATFORM

Salesforce provides the cloud platform used to build the Farm Management System. Setup and Object Manager provide configuration tools for objects, fields, relationships, profiles, roles and users.

Lightning Experience provides the working interface, while reports and dashboards provide analytical views. The platform therefore supports both configuration and day-to-day application use.

Farm Management System ■ Alternative Version

31. Lightning App

The Lightning App brings the main components of the Farm Management System into one navigation structure. The application can include Home, Farms, Crops, Farmers, Buyers, Reports and Dashboards. This arrangement places major record areas and analytics features together.

Users can move between object tabs and analytical views without leaving the application context. The Lightning App is important because a good data model still needs an accessible interface. The navigation structure should reflect the way users work with the project.

Farm and Crop records support agricultural data management, while Farmer and Buyer records support people and buyer information. Reports and Dashboards provide the analytical part of the application. Together, these navigation items create a simple user-facing structure and provide a practical starting point for daily use.

PROJECT DETAILS

■ The Lightning App brings the main components of the Farm Management System into one navigation structure.

■ The application can include Home, Farms, Crops, Farmers, Buyers, Reports and Dashboards.

■ This arrangement places major record areas and analytics features together.

■ Users can move between object tabs and analytical views without leaving the application context.

Section relevance: The information in 31. Lightning App forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration, security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

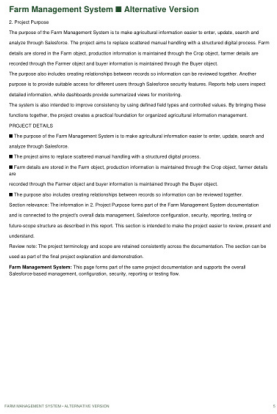

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 34

*Salesforce project screenshot / implementation reference*

# 30. DEVELOPER ORG ACTIVITY

The Developer Org is the working environment for building and testing the application. Custom objects are created first, followed by fields and relationships.

Custom tabs and the Lightning App establish navigation. Security and analytics components are configured after the main data structure is available, followed by testing.

Farm Management System ■ Alternative Version

2. Project Purpose

The purpose of the Farm Management System is to make agricultural information easier to enter, update, search and analyze through Salesforce. The project aims to replace scattered manual handling with a structured digital process. Farm details are stored in the Farm object, production information is maintained through the Crop object, farmer details are recorded through the Farmer object and buyer information is maintained through the Buyer object.

The purpose also includes creating relationships between records so information can be reviewed together. Another purpose is to provide suitable access for different users through Salesforce security features. Reports help users inspect detailed information, while dashboards provide summarized views for monitoring.

The system is also intended to improve consistency by using defined field types and controlled values. By bringing these functions together, the project creates a practical foundation for organized agricultural information management.

PROJECT DETAILS

■ The purpose of the Farm Management System is to make agricultural information easier to enter, update, search and analyze through Salesforce.

■ The project aims to replace scattered manual handling with a structured digital process.

■ Farm details are stored in the Farm object, production information is maintained through the Crop object, farmer details are

recorded through the Farmer object and buyer information is maintained through the Buyer object.

■ The purpose also includes creating relationships between records so information can be reviewed together.

Section relevance: The information in 2. Project Purpose forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration, security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM - ALTERNATIVE VERSION 5

*Salesforce project screenshot / implementation reference*

# 31. PROFILES

Profiles control the permissions available to Salesforce users. The project design uses role-specific profiles based on the Standard User profile for Farm Manager and Sales Department responsibilities.

Profiles form one part of the security model and work together with roles, users and sharing rules. Their configuration should match the responsibilities of each user group.

*Salesforce project screenshot / implementation reference*

# 32. ROLE HIERARCHY

The role hierarchy represents the organizational access structure used by the project. The Farm Manager role is positioned under the CEO.

The hierarchy contributes to record visibility according to organizational responsibilities. It is different from a profile, because profiles control permissions while roles represent the organizational structure.

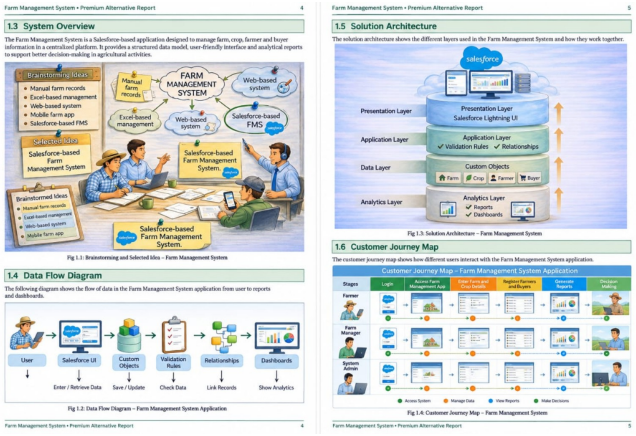

*Salesforce project screenshot / implementation reference*

# 33. USERS

Users are created to provide individual access to the Salesforce application. A user is assigned an appropriate profile and role according to the project responsibilities.

User configuration connects the identity of the person using the application with the project's permission and organizational structure. User access should be checked during security testing.

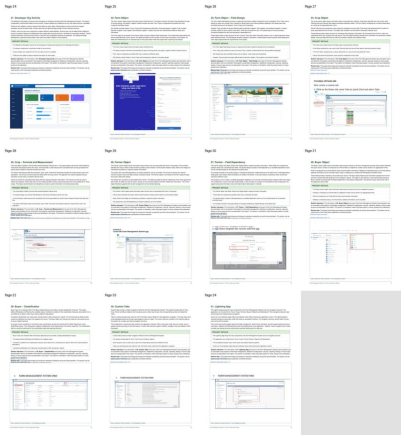

*Salesforce project screenshot / implementation reference*

# 34. SHARING RULES

Sharing rules provide additional record access when the standard access configuration does not provide the required collaboration. The project includes controlled sharing for specific business areas.

Crop records are shared with the Farm Manager using Read/Write access, while Buyer records are shared with the Sales Department using Read/Write access. These rules support collaboration within the defined project scope.

*Salesforce project screenshot / implementation reference*

# 35. SECURITY MODEL

The security model combines profiles, roles, users and sharing rules. Each component contributes a different part of access control.

Profiles define permissions, roles support organizational visibility, users provide individual assignments and sharing rules extend access where required. These settings should be reviewed together rather than independently.

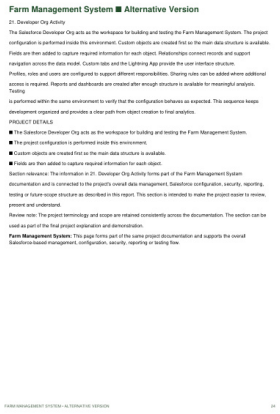

*Salesforce project screenshot / implementation reference*

# 36. REPORTS

Reports organize Salesforce records into detailed views. The project includes a Farmer with Farms report that combines farmer and farm information.

Another report uses Crops and Buyers according to the project configuration. Report columns, filters and available records should be checked as part of implementation testing.

**Farm Management System ■ Alternative Version**

21. Developer Org Activity

The Salesforce Developer Org acts as the workspace for building and testing the Farm Management System. The project configuration is performed inside this environment. Custom objects are created first so the main data structure is available. Fields are then added to capture required information for each object. Relationships connect records and support navigation across the data model. Custom tabs and the Lightning App provide the user interface structure. Profiles, roles and users are configured to support different responsibilities. Sharing rules can be added where additional access is required. Reports and dashboards are created after enough structure is available for meaningful analysis. Testing

is performed within the same environment to verify that the configuration behaves as expected. This sequence keeps development organized and provides a clear path from object creation to final analytics.

PROJECT DETAILS

■ The Salesforce Developer Org acts as the workspace for building and testing the Farm Management System.

■ The project configuration is performed inside this environment.

■ Custom objects are created first so the main data structure is available.

■ Fields are then added to capture required information for each object.

Developer Org Activity forms part of the Farm Management System documentation and is connected to the project's overall data management, Salesforce configuration , security, reporting, testing or future-scope structure as described in this report. This section is intended to make the project easier to review, present and understand.

Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

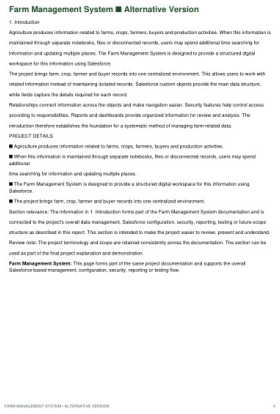

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 24

*Salesforce project screenshot / implementation reference*

# 37. DASHBOARD

The dashboard provides a summarized visual view of project information. The design includes a Gauge component based on the Farmers with Farms report.

Dashboards allow users to review selected information quickly while retaining access to the underlying report for more detailed inspection.

**Farm Management System ■ Alternative Version**

1. Introduction

Agriculture produces information related to farms, crops, farmers, buyers and production activities. When this information is maintained through separate notebooks, files or disconnected records, users may spend additional time searching for information and updating multiple places. The Farm Management System is designed to provide a structured digital workspace for this information using Salesforce.

The project brings farm, crop, farmer and buyer records into one centralized environment. This allows users to work with related information instead of maintaining isolated records. Review note: The project terminology and scope are retained consistently across the documentation. The section can be used as part of the final project explanation and demonstration.

**Farm Management System:** This page forms part of the same project documentation and supports the overall Salesforce-based management, configuration, security, reporting or testing flow.

FARM MANAGEMENT SYSTEM – ALTERNATIVE VERSION 4

*Salesforce project screenshot / implementation reference*

# 38. ANALYTICS WORKFLOW

The analytics workflow begins with records stored in the Farm, Crop, Farmer and Buyer objects. Users create or update records so the underlying information remains current.

Reports organize selected records into detailed views, while the dashboard summarizes report information. Users can move from a summary to the related records when further inspection is needed.

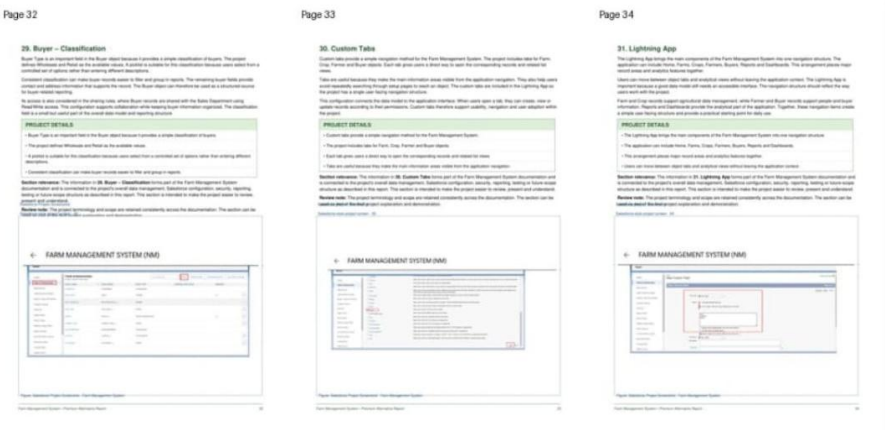

*Salesforce project screenshot / implementation reference*

# 39. TESTING STRATEGY

Testing checks whether the configured system behaves according to the project requirements. Object testing confirms that the four main objects are available, while field testing checks configured types and values.

Relationship testing verifies Farm-Farmer and Crop-Farm connections. Security testing checks users, profiles, roles and sharing rules, while report and dashboard testing checks analytical output.

# 40. FUNCTIONAL TEST CASES

Functional testing focuses on expected system behavior. Tests include opening objects, creating records, checking field values, verifying relationships and confirming appropriate user access.

Additional tests check sharing rules, reports and dashboard output. Repeating these tests after configuration changes helps maintain confidence in the completed setup.

# 41. PERFORMANCE AND RELIABILITY

Performance and reliability are considered as part of the project's non-functional requirements. Users should be able to navigate configured pages and open records without unnecessary complexity.

Reports and dashboards should display information from their underlying Salesforce configuration. Reliable relationships and consistent fields are important because they support navigation and analytics.

# 42. USER ADOPTION

User adoption depends on clear navigation, understandable fields and a workflow that matches user responsibilities. Custom tabs and the Lightning App provide a common entry point for the major functions.

Training and demonstration can help users understand record creation, updates, relationships, reports and dashboards. Adoption should be considered alongside configuration and testing.

# 44. ADVANTAGES, LIMITATIONS, CONCLUSION AND FUTURE SCOPE

The system centralizes farm, crop, farmer and buyer information in one Salesforce environment. Structured fields and relationships provide an organized method for maintaining and connecting records.

Profiles, roles and sharing rules support controlled access, while reports and dashboards provide analytical views. These features combine data management, security and reporting within the project's defined scope.

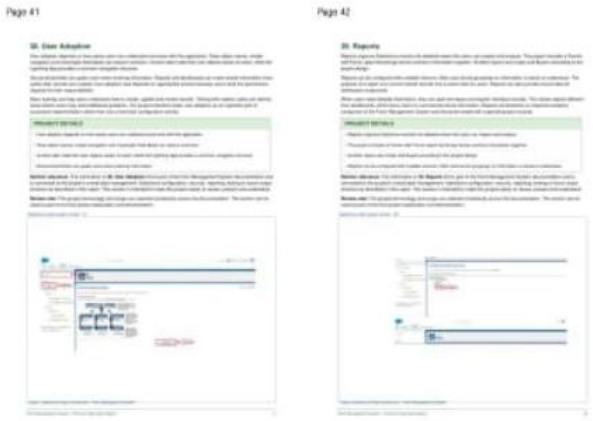

The project depends on Salesforce configuration, so users and administrators need familiarity with the platform. Training may be required before users can work confidently with the application.

The quality of reports and dashboards also depends on the completeness and correctness of stored records. Advanced mobile, IoT, weather and external integrations are outside the current implementation and would require additional development.

The Farm Management System demonstrates a structured Salesforce approach to agricultural information management. Farm, Crop, Farmer and Buyer objects provide the main data foundation, while fields and relationships connect the records.

Custom tabs and the Lightning App support navigation, and profiles, roles, users and sharing rules provide the access structure. Reports and dashboards provide analytical views, while testing checks the major configured components.

Future extensions identified by the project include mobile application integration, AI-based crop prediction, weather data, IoT connectivity, government scheme integration and market-price forecasting. These are proposed extensions rather than current project functions.

# 45. FINAL PROJECT REVIEW

The completed Farm Management System brings the main project components together in one Salesforce environment. The review covers the four custom objects, their fields and relationships, navigation through custom tabs and the Lightning App, and the configured security and analytics components.

The final review should confirm that Farm, Crop, Farmer and Buyer records can be created and maintained, that the configured relationships work as intended, and that users receive the access provided by their profiles, roles and sharing rules. Reports and dashboards should also be checked using the available project records.

This final page provides a concise review point for project submission and demonstration while keeping the scope limited to the Salesforce-based Farm Management System.
